 call it R_{BIG}

Therefore R_{BIG} is a finite space and dual space R^* can be viewed as a rectangle or a plane consisting of 2^{24} elements in it arranged in a lattice pattern.

Thus we can define our binary operations such as AND,OR, etc as two different things:

- 1) Means of traversing the grid by flipping some of the bits
- 2) vectors

We choose one boolean operator to measure similarity and go from there. Let it be XNOR. Other operations will have to do with adjusting weights as we arrived here from the weighted sum and the end goal is weighted average.

Ex4

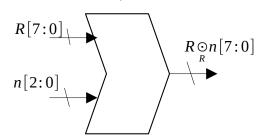

$$B=011_{2}$$
 $A=000_{2}$
 $A=000_{2}$
 $B=111_{2}$
 $A=000_{2}$
 $A=000_{2}$
 $A=000_{2}$
 $A=000_{2}$
 $A=000_{2}$
 $A>>1=100_{2}$
 $A=000_{2}$
 $A>>1=100_{2}$
 $A=000_{2}$

Can try different geometries/origin also. Actual notion of distance in this space may depend on the amount of such binary operations required to arrive from origin to any other point. Remember that we are looking for a point in this grid, that surely does exist, that is the closest approximation to the weighted average. Also remember once we contrived this space to be linear and dual by assuming 0.48 0.36 and 0.16 real numbers are independent (orthogonal) thus their products are equal to 0, all normal algebra went out the window.

Therefore \vec{v}, \vec{w} are orthogonal (hint from linear algebra) and these two operations (right shift with '1' fill and XNOR) span the entire lattice.

Denoise. Piecewise linear functions.

Recall $\overline{R} = a_1 \cdot \overline{R_1} + a_2 \cdot \overline{R_2} + a_3 \cdot \overline{R_3}$ is the value of the red component in the Bayer color filter array. Introduce noise as a constant in our linear equation:

Therefore now our Rbig looks like:

$$R^* = r_7^1 r_6^1 r_5^1 r_4^1 r_3^1 r_2^1 r_1^1 r_0^1 r_7^3 r_6^3 r_5^3 r_4^3 r_3^3 r_2^3 r_1^3 r_0^3 r_7^2 r_6^2 r_5^2 r_4^2 r_3^2 r_2^2 r_1^2 r_0^2 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0 \qquad \text{call it} \quad R_{BIG}$$

Now, taking it back to the inherent orthogonality of flips and shifts and keeping in mind their vector nature. As this is our new basis, and it is clear that the order of operations is strict, i.e.

$$f \circ q \neq q \circ f$$

Naturally, interpret our red component vectors as:

$$i = {0 \text{ induce shift} \atop 1 \text{ induce flip}}$$

Ex9

Px0, three surrounding red pixels

$$\begin{array}{ll} R_1 = 128_{10} = 10000000_2 & R_1^* = F(S(S(S(S(S(S(S(X(X)))))))) \\ R_2 = 53_{10} = 00110101_2 & R_2^* = S(S(F(F(S(F(S(F(X)))))))) \\ R_3 = 127_{10} = 01111111_2 & R_3^* = S(F(F(F(F(F(F(X(X)))))))) \end{array} \quad \begin{array}{ll} \text{Notion of most and least significance of bits comes to help here.} \\ \end{array}$$

Therefore our digital circuit core has to contain $2^8 = 256$ dual vectors.

So what we really meant with R* and Rbig is:

$$R^* = r_7^1 r_6^1 r_5^1 r_4^1 r_3^1 r_2^1 r_1^1 r_0^1 \wedge r_7^3 r_6^3 r_5^3 r_4^3 r_3^3 r_2^3 r_1^3 r_0^3 \wedge r_7^2 r_6^2 r_5^2 r_4^2 r_3^2 r_2^2 r_1^2 r_0^2 \qquad \text{call it} \quad R_{BIG} \quad \text{- wedge product} \quad \text{of linear functionals.}$$
